Homogenization at different linear scales, bounded martingales and the Two-Scale Shuffle limit

Kévin Santugini*

September 28, 2012

Abstract

In this paper, we consider two-scale limits obtained with increasing homogenization periods, each period being an entire multiple of the previous one. We establish that, up to a measure preserving rearrangement, these two-scale limits form a martingale which is bounded: the rearranged two-scale limits themselves converge both strongly in L^2 and almost everywhere when the period tends to $+\infty$. This limit, called the Two-Scale Shuffle limit, contains all the information present in all the two-scale limits in the sequence.

1 Introduction

Homogenization is used to study the solutions to equations when there are multiple scales of interest, usually a microscopic one and a macroscopic one. In particular, one may consider the solutions u_ε to a partial differential equation with locally ε-periodic coefficients and study their behavior as the small period ε tends to 0. Two-scale convergence, introduced by G. Nguetseng [10] and G. Allaire [1], is suited to study this particular subset of homogenization problems called periodic homogenization. It was later extended to the case of periodic surfaces by M. Neuss Radu [8, 9] and G. Allaire, A. Damlamian and U. Hornung [2]. It can also be used in the presence of periodic holes in the geometry, see [5, 6] or to homogenize multilayers [12, 13].

Intuitively, two-scale convergence introduces the concept of two-scale limit u_0 which is a function of both a macroscopic variable $\boldsymbol{x}$ —also called slow variable— and a microscopic p-periodic variable $\boldsymbol{y}$ —also called fast variable— such that, in some “meaning”, $\boldsymbol{x} \mapsto u_0(\boldsymbol{x}, \boldsymbol{x}/\varepsilon)$ is a good approximation of u_ε.

As indicated by its name, two-scale convergence captures the behavior at two scales: the macroscopic one and the $p\varepsilon$-periodic one. However, two-scale convergence does not capture all phenomena that happens at a scale linear in ε but only those whose length scale is $p\varepsilon/m$ where m is an integer. The two-scale limit of a sequence depends not only on the asymptotic scale, but also on the precise value of the chosen period. For example, any phenomena happening at the length scale of 2ε will not be fully apparent in the two-scale limit computed with period ε. The two-scale limit computed with period 2ε will contain no less —and might actually contain more— information than the two-scale limit computed with period ε. For example, the homogenization of $\sin(2\pi x/\varepsilon) + \sin(\pi x/\varepsilon)$ gives a two-scale limit of $u_0 : (x, y) \mapsto \sin(2\pi y)$ if computed with the homogenization period ε, *i.e.*, when $p = 1$, and $u_0 : (x, y) \mapsto \sin(2\pi y) + \sin(\pi y)$ if computed with the homogenization period 2ε, *i.e.*, when $p = 2$. Furthermore, if we choose $p = 1/2$, then the two-scale limit is none other than the null function. Worse, the scale factor p could be irrational.

The choice of the scale factor p used in the homogenization process is therefore of utmost importance in two-scale convergence. Using a badly chosen scale factor p may and will often cause a huge loss of information. At worst, we recover no more information than the one obtained by the standard weak L^2 limit: if $p\varepsilon$ is the correct choice of homogenization period, the two-scale limit computed with period $\lambda p\varepsilon$ where λ is an irrational number should, intuitively, carry no information about what happens at scale $p\varepsilon$.

Fortunately, there is usually a natural choice of period: the coefficients of the partial differential equation are often chosen locally ε-periodic. The most natural choice is to choose $p = 1$, *i.e.*, to consider the correct microscopic scale for u_ε is ε itself. If there are two important periods to consider $p\varepsilon$ and $p'\varepsilon$, the intuitive solution is to choose a period that is an entire multiple of both. However, this can only be done if the ratio p/p' between the two scale factors is a rational number.

When the two-scale limit depends on the fast variable, we may consider an homogenization period of $p_2\varepsilon$ instead of $p_1\varepsilon$ where p_2/p_1 is a positive integer. The two-scale limit computed with the homogenization period $p_2\varepsilon$ contains more information than the two-scale limit computed with the homogenization period $p_1\varepsilon$. It is then natural to study the behavior of the two-scale limit as the scale factor tends to $+\infty$. G. Allaire and C. Conca studied in [3] a similar problem and established, for an elliptic problem, the behavior of the spectra of the equation satisfied by the two-scale limit as the scale factor p goes to $+\infty$. G. Ben Arous and H. Owhadi [4] studied the behavior of the Brownian motion in a periodic potential using multiscale homogenization when the ratio between two successive scales is bounded from above and below.

In this paper, we consider various two-scale limits, each computed with a different homogenization period. In particular, we consider a sequence of periods $(p_n)_{n\in\mathbb{N}}$ such that for all integers n, p_{n+1}/p_n is a positive integer and we study the two-scale limit of $(u_\varepsilon)_{\varepsilon>0}$ computed with the homogenization period $p_n\varepsilon$. This two-scale limit, denoted u_{0,p_n}, is p_n-periodic in each component of its fast variable. Since p_{n+1} is always an entire multiple of p_n, one can always recover the two-scale limit u_{0,p_n} from the two scale limit $u_{0,p_{n+1}}$. If $p_{n+1} = m_n p_n$ and in dimension $d \geq 1$:

$$u_{0,p_n}(\boldsymbol{x},\boldsymbol{y}) = \frac{1}{m_n^d} \sum_{\boldsymbol{\alpha}\in[\![0,m_n-1]\!]^d} u_{0,p_{n+1}}(\boldsymbol{x},\boldsymbol{y}+p_n\boldsymbol{\alpha}).$$

The sequence of two-scale limits $(u_{0,p_n})_{n\in\mathbb{N}}$ yields increasing information on the asymptotic behavior of $(u_\varepsilon)_{\varepsilon>0}$. A natural question is whether the two-scale limits u_{0,p_n} themselves converge whenever n tends to $+\infty$. *I.E.*, does there exist a function that carry the information of all the p_n-two-scale limits? The goal of our paper is to answer this question. The answer is positive. We show in this paper that the sequence of two-scale limits is, after a measure preserving rearrangement, a bounded martingale in L^2 and therefore converges both strongly in L^2 and almost everywhere to a function we call the Two-Scale Shuffle limit.

In §2, we remind the reader of previously known results: two-scale convergence and the convergence properties of bounded martingales. In §3, we show how the different two-scale limits are related to each other through martingale-like equalities and explain how to transform these two-scale limits to get a genuine martingale. This leads to our stating of our main theorem: Theorem 3.8 in which we show that in a certain meaning the two-scale limits themselves converge to the Two-Scale Shuffle limit. In addition, we also state in Corollary 3.9 that all the information present in all the two-scale limits is contained in the Two-Scale Shuffle limit. In §4, we use this result on the heat equation in multilayers with transmission conditions between adjacent layers and establish, for this particular example, the equation satisfied by the Two-Scale Shuffle limit in Theorem 4.1.

2 Notations, prerequisites and known results

Throughout this paper, if x is in $\mathbb{R}$, we denote by $\lfloor x \rfloor$ the integer part of x. We also denote by $[\![n_1, n_2]\!]$ the set $[n_1, n_2] \cap \mathbb{N}$. To make the present paper as self-contained as possible, we recall in this section known results on the two main mathematical tools we use to prove our main theorem: two-scale convergence in §2.1, and classical results on the convergence of bounded martingales in §2.2.

2.1 The classical notion of two-scale convergence

First, as in [1], we introduce some notations. In this paper, p always refer to a scale factor. It remains constant while taking the two-scale limit. However, the goal of this paper is to observe the behavior of the two-scale limits as p tends to $+\infty$.

By Ω, we denote a bounded open domain of $\mathbb{R}^d$ where $d \geq 1$. By Y_p, we denote the cube $[0, p]^d$. By $\mathrm{L}^2_\#(Y_p)$, we denote the space of measurable functions defined over $\mathbb{R}^d$, that are p-periodic in each variable and that are square integrable over Y_p. By $\mathcal{C}_\#(Y_p)$, we denote the set of continuous functions defined on $\mathbb{R}^d$ that are p-periodic in each variable.

We reproduce the now classical definition of two-scale convergence found in [1, 10]. For convenience, we added the scale factor p.

Definition 2.1 (Two-scale convergence)**.** Let p be a positive real. A sequence $(u_\varepsilon)_{\varepsilon>0}$ belonging to $\mathrm{L}^2(\Omega)$ is said to p-two-scale converge if there exists $u_{0,p}$ in $\mathrm{L}^2(\Omega \times Y_p)$ such that:

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(\boldsymbol{x}) \psi \left(\boldsymbol{x}, \frac{\boldsymbol{x}}{\varepsilon} \right) \mathrm{d}\boldsymbol{x} = \frac{1}{p^d} \int_\Omega \int_{Y_p} u_{0,p}(\boldsymbol{x}, \boldsymbol{y}) \psi(\boldsymbol{x}, \boldsymbol{y}) \, \mathrm{d}\boldsymbol{y} \, \mathrm{d}\boldsymbol{x}, \tag{2.1}$$

for all ψ in $\mathrm{L}^2(\Omega; \mathcal{C}_\#(Y_p))$.

It is a common abuse of notation to also designate by $u_{0,p}$ the unique extension of $u_{0,p}$ to $\Omega \times \mathbb{R}^d$ that is p-periodic in the last d variables.

G. Allaire, see [1], and G.Nguetseng, see [10], proved that any sequence of functions bounded in L^2 has a subsequence that two-scale converges. Let's reproduce this precise compactness result.

Theorem 2.2. *Let $(u_\varepsilon)_{\varepsilon>0}$ be a sequence of functions bounded in $\mathrm{L}^2(\Omega)$. Then, there exist $u_{0,p}$ in $\mathrm{L}^2(\Omega \times]0, p[^d)$ and a subsequence ε_k converging to 0 such that*

$$\lim_{k \to \infty} \int_\Omega u_{\varepsilon_k}(\boldsymbol{x}) \psi \left(\boldsymbol{x}, \frac{\boldsymbol{x}}{\varepsilon_k} \right) \mathrm{d}\boldsymbol{x} = \frac{1}{p^d} \int_\Omega \int_{Y_p} u_{0,p}(\boldsymbol{x}, \boldsymbol{y}) \psi(\boldsymbol{x}, \boldsymbol{y}) \, \mathrm{d}\boldsymbol{y} \, \mathrm{d}\boldsymbol{x}, \tag{2.2}$$

for all ψ *in* $\mathrm{L}^2(\Omega;\mathcal{C}_\#(Y_p))$.

Proof. See G. Allaire [1, Theorem 1.2] and G. Nguetseng [10, Theorem 2]. The presence of the scale factor p has no impact on the proof. □

We also have the classical proposition

Proposition 2.3. *Let* u_ε *p-two-scale converges to* $u_{0,p}$. *Then,*

$$\frac{1}{p^{d/2}}\|u_{0,p}\|_{\mathrm{L}^2(\Omega\times Y_p)} \leq \liminf_{\varepsilon\to 0}\|u_\varepsilon\|_{\mathrm{L}^2(\Omega)}.$$

Proof. See G. Allaire [1, Proposition 1.6]. The presence of the scale factor p has no impact on the proof. □

The next proposition is easy to derive from Theorem 2.2.

Proposition 2.4. *Let* $(p_n)_{n\in\mathbb{N}}$ *be an increasing sequence of positive real numbers. Let* $(u_\varepsilon)_{\varepsilon>0}$ *be a sequence of functions bounded in* $\mathrm{L}^2(\Omega)$. *Then, there exist a subsequence* $(\varepsilon_k)_{k\in\mathbb{N}}$ *converging to* 0, *and a sequence of functions* u_{0,p_n} *in* $\mathrm{L}^2(\Omega\times]0,p_n[^d)$ *such that, for any non-negative integer* n, *the sequence* $(u_{\varepsilon_k})_{k\in\mathbb{N}}$ p_n*-two-scale converges to* u_{0,p_n}. *I.E., such that for all integers* n*:*

$$\lim_{k\to\infty}\int_\Omega u_{\varepsilon_k}(\boldsymbol{x})\psi\left(\boldsymbol{x},\frac{\boldsymbol{x}}{\varepsilon_k}\right)\,\mathrm{d}\boldsymbol{x} = \frac{1}{p_n^d}\int_\Omega\int_{Y_{p_n}} u_{0,p_n}(\boldsymbol{x},\boldsymbol{y})\psi\left(\boldsymbol{x},\boldsymbol{y}\right)\,\mathrm{d}\boldsymbol{y}\,\mathrm{d}\boldsymbol{x},$$

for all ψ *in* $\mathrm{L}^2(\Omega;\mathcal{C}_\#(Y_{p_n}))$.

Proof. Apply Theorem 2.2 multiple times and proceed via diagonal extraction. □

Our goal in this paper is to study the limit of u_{0,p_n} as p_n tends to $+\infty$.

2.2 Convergence of bounded martingales

In this section, we recall the notions of probability theory needed to prove our main theorem. In particular, we are interested in using the convergence properties of bounded martingales. For more details, the reader may consult [7]. We assume the reader to be familiar with the notions of σ-field and σ-additivity in measure theory.

We use the following common notations:

- If C is a subset of $\mathcal{P}(X)$, we denote by $\sigma(C)$ the smallest σ-field in X that contains C.

- If D is a topological space, we denote by $\mathcal{B}(D)$ the set of all Borel sets in D, *i.e.*, the smallest σ-field containing all the open subsets of D.

Definition 2.5 (Measurable space)**.** A pair $(X, \mathcal{F})$ is said to be a measurable space if $\mathcal{F}$ is a σ-field in X.

Definition 2.6 (Measure space)**.** A triplet $(X, \mathcal{F}, \mu)$ is said to be a measure space if $(X, \mathcal{F})$ is a measurable space and if μ is a positive σ-additive measure on $(X, \mathcal{F})$.

A measure space $(X, \mathcal{F}, \mu)$ is said to be finite if $\mu(X) < +\infty$. A measure space $(X, \mathcal{F}, \mu)$ is said to be σ-finite if X is the countable union of $\mathcal{F}$-measurable sets of finite measure. A measure space $(X, \mathcal{F}, \mathbb{P})$ is said to be a probability space if $\mathbb{P}(X) = 1$.

We start by recalling the definition of conditional expectation, see [7, ch. 6, Theorem 6.1] for more details. Usually, the conditional expectation is defined for probability spaces. The definition extends without problem to finite measure spaces and even, to some extent, to σ-finite measure spaces.

Definition 2.7 (Conditional expectation)**.** Let $(X, \mathcal{F}, \mu)$ be a measure space with μ being positive and σ-additive. Let $\mathcal{G}$ be a σ-field such that $\mathcal{G} \subset \mathcal{F}$ and $(X, \mathcal{G}, \mu)$ is also σ-finite. Let $f : X \to \mathbb{R}$ be $\mathcal{F}$-measurable and in $L^1_{\mathrm{loc}}(X, \mu)$. The conditional expectation of f with respect to the σ-field $\mathcal{G}$ is denoted by $\mathbb{E}(f|\mathcal{F})$, and is defined as the unique, up to a modification on a set of null measure, $\mathcal{G}$-measurable function g such that

$$\int_B g(\omega)\,\mathrm{d}\omega = \int_B f(\omega)\,\mathrm{d}\omega,$$

for all B in $\mathcal{G}$.

The existence of the conditional expectation is given by Radon-Nikodym theorem. The measure μ need not be a probability measure. However, to apply Radon-Nykodim theorem, $(X, \mathcal{G}, \mu)$ needs to be σ-finite, hence the restriction in the definition. A statement and a proof of the Radon-Nikodym theorem can be found in [11, Theorem 6.10].

It is not enough that $(X, \mathcal{F}, \mu)$ be σ-finite in Definition 2.7.

Remark 2.8. When $\mathcal{G} \subset \mathcal{F}$, it does not follow from $(X, \mathcal{F}, \mu)$ being σ-finite that $(X, \mathcal{G}, \mu)$ is also σ-finite. A counter-example is easily obtained by setting $\mathcal{G} := \{\emptyset, X\}$ whenever $\mu(X) = +\infty$.

In our main theorem, we restrict ourselves to the case of finite measures. However, Remark 2.8 will explain why the martingale approach doesn't quite work for the most natural attempt to define a convergence for two-scale limits, see §3.1.

In order to define martingales, we remind the reader of the definition of filtration. We limit ourselves to filtrations indexed by the set $\mathbb{N}$. See [7, ch. 7, p. 120] for more details.

Definition 2.9 (Filtrations)**.** Let $(X, \mathcal{F})$ be a measurable space. A sequence $(\mathcal{F}_n)_{n\in\mathbb{N}}$ of σ-fields, $\mathcal{F}_n \subset \mathcal{F}$ is a filtration if, for all non-negative integers n, $\mathcal{F}_n$ is a subset of $\mathcal{F}_{n+1}$.

We now recall the definition of martingales.

Definition 2.10 (Martingales)**.** Let $(X, \mathcal{F}, \mu)$ be a σ-finite measure space. Let $(\mathcal{F}_n)_{n\in\mathbb{N}}$ be a filtration on $(X, \mathcal{F}, \mu)$ such that $(X, \mathcal{F}_0, \mu)$ is σ-finite.

A sequence $(f_n)_{n\in\mathbb{N}}$ is said to be a $(\mathcal{F}_n)_{n\in\mathbb{N}}$-martingale, if for all non-negative integers n and j,

$$f_n = \mathbb{E}(f_{n+j}|\mathcal{F}_n).$$

I.E., if f_n is $\mathcal{F}_n$-measurable and if for all F in $\mathcal{F}_n$:

$$\int_F f_n(\omega)\,\mathrm{d}\omega = \int_F f_{n+j}(\omega)\,\mathrm{d}\omega \tag{2.3}$$

We now reproduce the convergence results of bounded martingales:

Theorem 2.11 (Convergence of bounded martingales)**.** *Let $(X, \mathcal{F}, \mu)$ be a measure space with finite measure. Let $(\mathcal{F}_n)_{n\in\mathbb{N}}$ be a filtration on the measurable space $(X, \mathcal{F})$. Let q be in $]1, +\infty[$. Let $(f_n)_{n\in\mathbb{N}}$ be a $(\mathcal{F}_n)_{n\in\mathbb{N}}$-martingale such that the sequence $(f_n)_{n\in\mathbb{N}}$ is bounded in $L^q(X)$. Then, the sequence $(f_n)_{n\in\mathbb{N}}$ converges both almost everywhere and strongly in $L^q(X, \mathbb{P})$.*

Proof. See [7, Corollary 7.22] for the strong L^q convergence. The almost everywhere convergence is stated in [7, Theorem 7.18] and holds even for $q = 1$. While these two results are stated for probability measures, the finite measures case is easily deduced from the probability measure case by considering the probability measure $\mu(\cdot)/\mu(X)$. ☐

The above theorem extends, at least partially, to σ-finite measures:

Remark 2.12. In Theorem 2.11, if the probability space $(X, \mathcal{F}, \mathbb{P})$ is replaced with σ-finite measure space $(X, \mathcal{F}, \mu)$ such that $(X, \mathcal{F}_0, \mu)$ is also σ-finite, then the bounded martingales converge almost everywhere and at least in L^q_{loc}. It is unknown to the author if the strong L^q convergence can be generalized to the σ-finite case.

3 Two-scale limits and bounded martingales

In this section, we always assume both of the following assumptions are satisfied:

Assumption 3.1 (Integer scale ratios)**.** We are given a real sequence $(p_n)_{n\in\mathbb{N}}$, such that for all n in $\mathbb{N}$, $p_n > 0$ and p_{n+1} is an entire multiple of p_n. Moreover, we set for $n \geq 1$, $m_n := p_n/p_{n-1} \in \mathbb{N}$, and for $n \geq 0$, $M_n := p_n/p_0 \in \mathbb{N}$.

Assumption 3.2. We are given a sequence of functions $(u_\varepsilon)_{\varepsilon>0}$ bounded in $\mathrm{L}^2(\Omega)$ and a decreasing sequence of positive $(\varepsilon_k)_{k\in\mathbb{N}}$ such that the sequence $(u_{\varepsilon_k})_{k\in\mathbb{N}}$ p_n-two-scale converges for all integers n to a function u_{0,p_n} that belongs to $\mathrm{L}^2(\Omega\times]0,p_n[^d)$.

This last assumption is justified by Proposition 2.4.

Our goal is to study the convergence of the two-scale limits u_{0,p_n} when n goes to infinity. In this section, we proceed as follows: we begin by establishing a useful equality that looks like a martingale equality in §3.1, then we propose a rearrangement of the two-scale limits in §3.2, and finally propose another rearrangement of the two-scale limits in §3.3, the shuffle, which transform the sequence of two-scale limits into a bounded martingale.

3.1 An almost martingale equality

We start with a simple but essential proposition.

Proposition 3.3. *Suppose both assumptions 3.1 and 3.2 are satisfied. Then, for all j in $\mathbb{N}$, all n in $\mathbb{N}$, almost all $\boldsymbol{x}$ in Ω and almost all $\boldsymbol{y}$ in Y_p:*

$$u_{0,p_n}(\boldsymbol{x},\boldsymbol{y}) = \left(\frac{p_n}{p_{n+j}}\right)^d \sum_{\boldsymbol{\alpha}\in[\![0,p_{n+j}/p_n-1]\!]^d} u_{0,p_{n+j}}(\boldsymbol{x},\boldsymbol{y}+\boldsymbol{\alpha}p_n). \tag{3.1}$$

Proof. Let ϕ belong to $\mathcal{C}^\infty(\overline{\Omega}\times\mathbb{R}^d)$ be p_n-periodic in the last d variables. Since p_{n+j}/p_n is an integer, ϕ is also p_{n+j}-periodic in the last d variables. We take the limit of $\int_\Omega u_\varepsilon(\boldsymbol{x})\phi(\boldsymbol{x},\boldsymbol{x}/\varepsilon)\,\mathrm{d}\boldsymbol{x}$, as ε tends to 0, in the sense of two-scale convergence for both scale factors p_{n+j} and p_n:

$$\frac{1}{p_n^d}\int_\Omega\int_{Y_{p_n}} u_{0,p_n}(\boldsymbol{x},\boldsymbol{y})\phi(\boldsymbol{x},\boldsymbol{y})\,\mathrm{d}\boldsymbol{y}\,\mathrm{d}\boldsymbol{x} =$$

$$= \frac{1}{p_{n+j}^d}\int_\Omega\int_{Y_{p_{n+j}}} u_{0,p_{n+j}}(\boldsymbol{x},\boldsymbol{y})\phi(\boldsymbol{x},\boldsymbol{y})\,\mathrm{d}\boldsymbol{y}\,\mathrm{d}\boldsymbol{x}, =$$

$$= \frac{1}{p_{n+j}^d}\int_\Omega\int_{Y_{p_n}} \Bigg(\sum_{\boldsymbol{\alpha}\in([\![0,p_{n+j}/p_n-1]\!]^d} u_{0,p_{n+j}}(\boldsymbol{x},\boldsymbol{y}+\boldsymbol{\alpha}p)\Bigg)\phi(\boldsymbol{x},\boldsymbol{y})\,\mathrm{d}\boldsymbol{y}\,\mathrm{d}\boldsymbol{x}. \quad \square$$

The most natural approach is to consider the u_{0,p_n} as functions defined over $\Omega \times \mathbb{R}^d$ and to study their convergence in some meaning in $\Omega \times \mathbb{R}^d$. Such a convergence result would be ideal as the intuitive meaning of the limit would be easy to grasp. Equality (3.1) is similar to the martingale defining equality (2.3). Would it be possible to use the classical convergence properties of martingales, see Theorem 2.11, to prove the existence of a limit to the u_{0,p_n}? Unfortunately, the martingale approach doesn't work in this setting but the attempt is, nevertheless, instructive. First, we try to construct a filtration $(\mathcal{F}_n)_{n\in\mathbb{N}}$ for the u_{0,p_n}. For all positive integer n, the u_{0,p_n} are p_n-periodic with respect to the last d variables. Let $\mathcal{F}_n$ be the set of all Borel subsets of $\Omega \times \mathbb{R}^d$ that are invariant by translation of $\pm p_n$ along any of the last d directions of $\Omega \times \mathbb{R}^d$. Clearly, u_{0,p_n} is $\mathcal{F}_n$-measurable. However, the measure space $(\Omega \times \mathbb{R}^d, \mathcal{F}_n, \mu)$ where μ is the Lebesgue measure is not σ-finite: any $\mathcal{F}_n$ measurable subset of $\Omega \times \mathbb{R}^d$ is either of null measure or of infinite measure. Therefore, the concept of $(\mathcal{F}_n)_{n\in\mathbb{N}}$-martingale is ill-defined, see Definition 2.10 and Remark 2.8. Should we attempt to verify whether the martingale defining equality (2.3) hold, we would get either $+\infty$ or 0 on both sides of the equation.

However, the martingale defining equality (2.3) is satisfied if one replaces the Lebesgue integral of $\mathbb{R}^d$ by the limit of the mean over a ball as its radius tends to $+\infty$. *I.E.*, we have for all F in $\mathcal{F}_n$

$$\lim_{R\to+\infty} \frac{1}{|B(\mathbf{0},R)|} \int_\Omega \int_{B(\mathbf{0},R)} \mathbb{1}\{(\boldsymbol{x},\boldsymbol{y}) \in F\} u_{0,p_n}(\boldsymbol{x},\boldsymbol{y}) \,\mathrm{d}\boldsymbol{y} \,\mathrm{d}\boldsymbol{x} = \\ = \lim_{R\to+\infty} \frac{1}{|B(\mathbf{0},R)|} \int_\Omega \int_{B(\mathbf{0},R)} \mathbb{1}\{(\boldsymbol{x},\boldsymbol{y}) \in F\} u_{0,p_{n+j}}(\boldsymbol{x},\boldsymbol{y}) \,\mathrm{d}\boldsymbol{y} \,\mathrm{d}\boldsymbol{x},$$

where $B(\mathbf{0},R)$ is the open ball of $\mathbb{R}^d$ centered on 0 and of radius R and where $|A|$ is the Lebesgue measure of set A. Unfortunately, we were unable to derive a direct convergence result using this pseudo-martingale equality. To proceed further, we need to transform the two-scale limits u_{0,p_n} in order to get genuine martingales.

3.2 Rearrangement of the two-scale limits with integers

In the previous section, we established a “martingale-like” equality for the two-scale limits u_{0,p_n}. To get genuine martingales in the sense of Definition 2.10, we need to rearrange the u_{0,p_n}. While we are unable to prove a convergence for the rearrangement of the two-scale limits presented in this section, the ideas behind this rearrangement provide insight on the next section where we introduce another rearrangement and prove its convergence.

In this section, we rearrange the u_{0,p_n} by introducing a new variable $\boldsymbol{\alpha}$ that belongs to $\mathbb{Z}^d$. The rearrangement, denoted by v_{p_n}, depends on the slow variable $\boldsymbol{x} \in \Omega$, on a fast variable $\boldsymbol{y} \in [0, p_0[^d$, and on the new variable $\boldsymbol{\alpha}$. To rearrange the u_{0,p_n} into the v_{p_n}, we subdivide $\Omega \times [0, p_n[^d$ into $M_n^d = (p_n/p_0)^d$ sets $\Omega \times \prod_{i=1}^d [\alpha_i, \alpha_i + p_0[$. Each of these sets is the product of Ω with an hypercube indexed by $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_d)$ and we define $v_{p_n}(\cdot, \boldsymbol{\alpha}, \cdot)$ as taking in $\Omega \times [0, p_0[^d$ the same values u_{0,p_n} does in $\Omega \times \prod_{i=1}^d [\alpha_i, \alpha_i + p_0[$. The variable $\boldsymbol{y}$ represents the position of the fast variable inside each hypercube. *I.E.*, we set:

$$\begin{aligned} v_{p_n} : \Omega \times \mathbb{Z}^d \times Y_{p_0} &\to \mathbb{R}, \\ (\boldsymbol{x}, \boldsymbol{\alpha}, \boldsymbol{y}) &\mapsto u_{0,p_n}(\boldsymbol{x}, \boldsymbol{y} + p_0 \boldsymbol{\alpha}). \end{aligned}$$

We have the following proposition

Proposition 3.4. *For all n in $\mathbb{N}$, for almost all $\boldsymbol{x}$ in Ω and $\boldsymbol{y}$ in Y_{p_0}, the $\boldsymbol{\alpha}$-indexed sequence $(v_{p_n}(\boldsymbol{x}, \boldsymbol{\alpha}, \boldsymbol{y}))_{\boldsymbol{\alpha} \in \mathbb{Z}^d}$ is M_n-periodic in each direction of $\boldsymbol{\alpha}$. Moreover:*

$$v_{p_n}(\boldsymbol{x}, \boldsymbol{\alpha}, \boldsymbol{y}) = \left(\frac{M_n}{M_{n+j}} \right)^d \sum_{\boldsymbol{\beta} \in [\![0, M_{n+j}/M_n - 1]\!]^d} v_{p_{n+j}}(\boldsymbol{x}, \boldsymbol{\alpha} + M_n \boldsymbol{\beta}, \boldsymbol{y}), \qquad (3.2)$$

for all $\boldsymbol{\alpha}$ in $\mathbb{Z}^d$.

Proof. This is a direct consequence of Proposition 3.3. ☐

This in turn should encourage us to look at the following problem.

Problem 3.5. *Let's call "imbricated $(M_n)_n$-periodic d-dimensional sequences", sequences that satisfy the following properties $(t_{n,\boldsymbol{\alpha}})_{n \in \mathbb{N}, \boldsymbol{\alpha} \in \mathbb{Z}^d}$ such that*

- *for all n in $\mathbb{N}$, the $\boldsymbol{\alpha}$-indexed sequence $(t_{n,\boldsymbol{\alpha}})_{\boldsymbol{\alpha} \in \mathbb{Z}^d}$ is M_n-periodic in each direction of $\boldsymbol{\alpha}$, i.e. such that for all n in $\mathbb{N}$, for all $\boldsymbol{\alpha}$ in $\mathbb{Z}^d$, and for all $\boldsymbol{\beta}$ in $\mathbb{Z}^d$:*
  $$t_{n,\boldsymbol{\alpha}} = t_{n,\boldsymbol{\alpha} + M_n \boldsymbol{\beta}},$$
- *for all n in $\mathbb{N}$, and for all $\boldsymbol{\alpha}$ in $\mathbb{Z}^d$,*
  $$t_{n,\boldsymbol{\alpha}} = \left(\frac{M_n}{M_{n+j}} \right)^d \sum_{\boldsymbol{\beta} \in [\![0, M_{n+j}/M_n - 1]\!]^d} t_{n+j, \boldsymbol{\alpha} + M_n \boldsymbol{\beta}}.$$

Study the convergence of $(t_{n,\boldsymbol{\alpha}})_{n\in\mathbb{N},\boldsymbol{\alpha}\in\mathbb{Z}^d}$ *as* n *tends to* $+\infty$*. Under which condition does there exist a sequence* $t_{\infty,\boldsymbol{\alpha}}$ *such that for all non-negative integers* n

$$t_{n,\boldsymbol{\alpha}} = \lim_{N\to+\infty} \frac{1}{N^d} \sum_{\boldsymbol{\beta}\in[\![0,N-1]\!]^d} t_{\infty,\boldsymbol{\alpha}+M_n\boldsymbol{\beta}}.$$

or such that

$$t_{n,\boldsymbol{\alpha}} = \lim_{N\to+\infty} \frac{1}{2^d N^d} \sum_{\boldsymbol{\beta}\in[\![-N,N-1]\!]^d} t_{\infty,\boldsymbol{\alpha}+M_n\boldsymbol{\beta}}.$$

or both?

By Proposition 3.4, for almost all $\boldsymbol{x}$ in Ω and $\boldsymbol{y}$ in Y_{p_0}, the $\boldsymbol{\alpha}$-indexed sequences $(v_{p_n}(\boldsymbol{x},\boldsymbol{\alpha},\boldsymbol{y}))_{\boldsymbol{\alpha}\in\mathbb{Z}^d}$ are imbricated $(M_n)_n$-periodic d-dimensional sequences. Solving Problem 3.5 would be the first step in having a very elegant limit to the v_{p_n} as a function defined on $\Omega\times\mathbb{Z}^d\times Y_{p_0}$. Unfortunately, we do not have an answer for Problem 3.5. While this sequence is morally a martingale with respect to the filtration made of the σ-fields $\{\boldsymbol{\alpha}+M_n\mathbb{Z}^d, \boldsymbol{\alpha}\in[\![0,M_n-1]\!]^d\}$, it technically is not: we have the same problem we had in the previous section. To conclude with bounded martingales on the convergence, we would need a measure μ on $\mathbb{Z}^d$ such that $\mu(\mathbb{Z}^d)=1$, invariant by translation and such that $\mu(m\mathbb{Z}^d)=1/m$ whenever m is an integer different from 0. Such a measure cannot be σ-additive. If we remove the σ additivity constraint, then μ exists: just set

$$\mu(A) := \lim_{N\to+\infty} \frac{\#(A\cap[\![-N,N]\!]^d)}{(2N+1)^d}.$$

It is unknown to the author if bounded martingales converge when they are defined on a non σ-additive measure. To avoid that problem, we introduce, in the next section, a different less natural rearrangement for the u_{0,p_n}, the shuffle, for which we finally prove a convergence result.

3.3 Shuffle rearrangement of two-scale limits

In the previous section, we investigated a rearrangement where the set $\Omega\times[0,p_n[^d$ was subdivided into M_n^d subsets indexed by $\boldsymbol{\alpha}\in\mathbb{Z}^d$. In this section, we finally construct a rearrangement, the shuffle, that results in a bounded martingale; thus establishing a convergence result for the p_n-two-scale limits as n tends to $+\infty$. To do so, we replace the variable $\boldsymbol{\alpha}$ belonging to $\mathbb{Z}^d$ with the variable $\boldsymbol{y}'$ that belongs to $[0,1[^d$. Like the variable $\boldsymbol{\alpha}$ of the previous section, the variable $\boldsymbol{y}'$ indicates which hypercube of edge length p_0 we consider. The variable $\boldsymbol{y}$ remains unchanged and continue to represent the

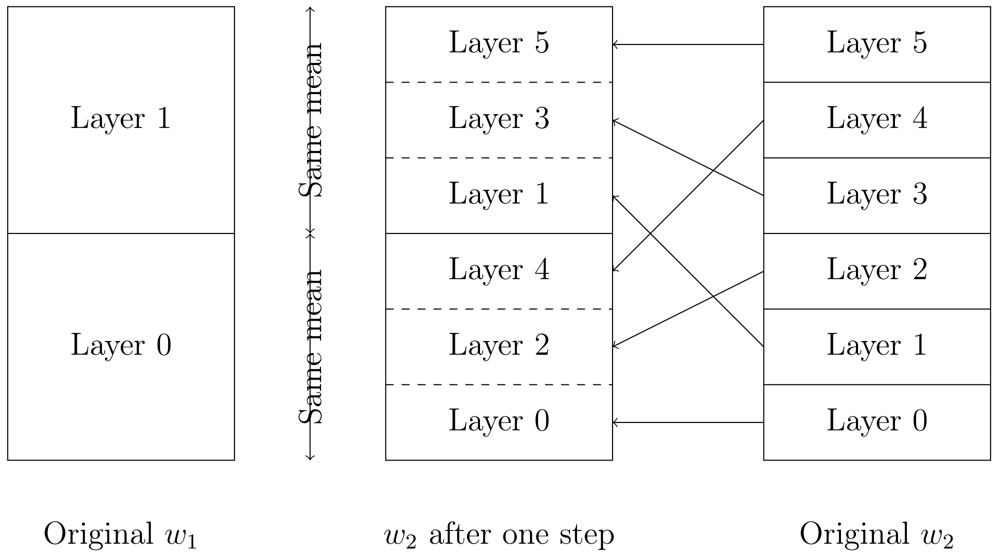

Figure 1: One step of the measure preserving rearrangement $M_1 = 2$ and $M_2 = 6$

location inside the hypercube indexed by $\boldsymbol{y}'$. We set for $\boldsymbol{x}$ in Ω, $\boldsymbol{y}$ in $[0, p_0]^d$ and $\boldsymbol{y}'$ in $[0,1]^d$,

$$w_n(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{y}') := v_{p_n}(\boldsymbol{x}, \boldsymbol{\alpha}(\boldsymbol{y}'), \boldsymbol{y}),$$

where $\boldsymbol{\alpha}(\boldsymbol{y}')_i = \lfloor M_n \boldsymbol{y}'_i \rfloor$ for all integers i in $[\![1, d]\!]$. Using Proposition 3.4, we derive that for almost all $\boldsymbol{x}$ in Ω, $\boldsymbol{y}$ in Y_{p_0}, (j, n) in $\mathbb{N}^2$, and $\boldsymbol{\alpha}$ in $[\![0, M_n - 1]\!]^d$

$$\int_{\prod_{i=1}^d [\frac{\alpha_i}{M_n}, \frac{\alpha_i+1}{M_n}[} w_n(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}' = \\ = \sum_{\boldsymbol{\beta} \in [\![0, \frac{M_{n+j}}{M_n} - 1]\!]^d} \int_{\prod_{i=1}^d [\frac{M_n\beta_i + \alpha_i}{M_{n+j}}, \frac{M_n\beta_i+\alpha_i+1}{M_{n+j}}[} w_{n+j}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'. \quad (3.3)$$

To transform the w_n into martingales, we need to shuffle the hypercubes as in Figure 1 where, to simplify the drawing, homogenization was only performed on the last component of $\mathbb{R}^d$, hence the presence of layers instead of hypercubes. In that figure, we show one step of the rearrangement. As seen in the drawing, each step of the rearrangement is measure preserving, therefore the full rearrangement is also measure preserving. We need $n - 1$ such steps to fully rearrange w_n.

To define rigorously this rearrangement, we begin by defining the function

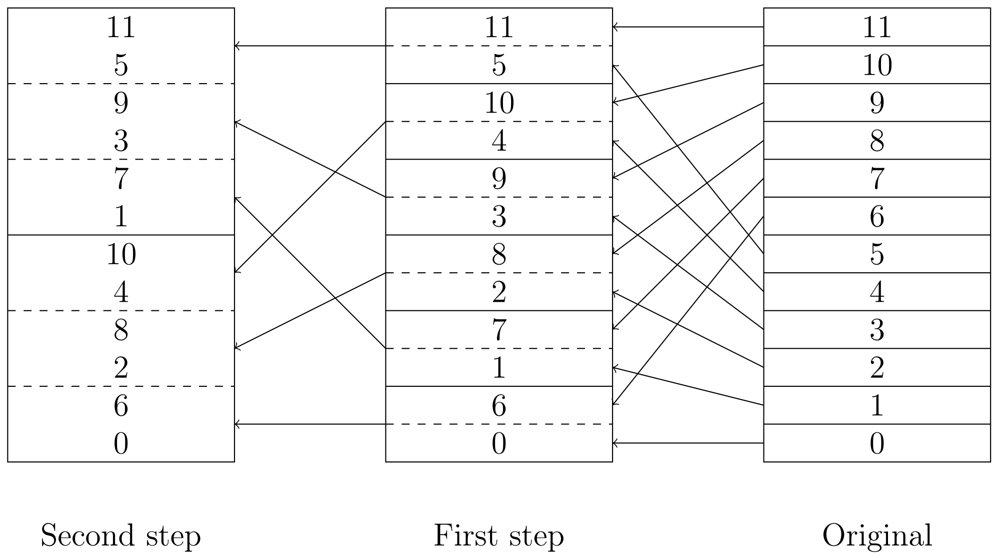

Figure 2: Two steps of the measure preserving rearrangement $M_1 = 2$, $M_2 = 6$ and $M_3 = 12$

that maps the rearranged layer index onto the unrearranged layer index:

$$\begin{aligned} R_{M,m} :& [\![0, Mm-1]\!] \to [\![0, Mm-1]\!] \\ & i \mapsto M \cdot (i \mod m) + \left\lfloor \frac{i}{m} \right\rfloor . \end{aligned} \tag{3.4a}$$

The application $R_{M,m}$ maps $km+j$ to $jM+k$ when k belongs to $[\![0, M-1]\!]$ and j belongs to $[\![0, m-1]\!]$. We also have $R_{M,m} \circ R_{m,M} = R_{m,M} \circ R_{M,m} = \mathrm{Id}$.

Then, we set the function that maps the rearranged layer onto the unrearranged one:

$$\begin{aligned} h^*_{M,m} : & [0,1[\to [0,1[, \\ & y' \mapsto \frac{R_{M,m}(\lfloor Mmy' \rfloor)}{Mm} + \left(y' - \frac{\lfloor Mmy' \rfloor)}{Mm} \right). \end{aligned} \tag{3.4b}$$

This represents only one step of the rearrangement on one component. For hypercubes, the permutation is the same but is done componentwise: we set

$$\begin{aligned} h_{M,m} : &]0,1[^d \to]0,1[^d, \\ & (y'_1, \dots, y'_n) \mapsto (h^*_{M,m}(y'_1), \dots, h^*_{M,m}(y'_n)). \end{aligned}$$

And obtain one step of the rearrangement on all d components. For the complete rearrangement on one component, see Figure 2, we set

$$H_n^* := h^*_{M_{n-1},m_n} \circ \ldots \circ h^*_{M_1,m_2} \circ h^*_{M_0,m_1}. \tag{3.4c}$$

To get the complete rearrangement on all components we set

$$\begin{aligned} H_n\colon & [0,1[^d \to [0,1[^d, \\ (y_1',\ldots,y_n') & \mapsto (H_n^*(y_1'),\ldots,H_n^*(y_n')). \end{aligned} \tag{3.4d}$$

We also have

$$H_n = h_{M_{n-1},m_n} \circ \ldots \circ h_{M_1,m_2} \circ h_{M_0,m_1}.$$

The function H_n shuffles the hypercubes $\prod_{i=1}^d [\beta_i/M_n, (\beta_i+1)/M_n[$, hence we call H_n the shuffle function.

Finally, we define

$$\widetilde{w}_n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}') := w_n(\boldsymbol{x},\boldsymbol{y},H_n(\boldsymbol{y}')). \tag{3.5}$$

This measure preserving rearrangement, the shuffle, is purposefully constructed so the $\widetilde{w}_n$ form a martingale for the following filtration of σ-fields $\mathcal{F}_n = \mathcal{B}(\Omega) \times \mathcal{B}([0,p_0]^d) \times \sigma\left\{\prod_{i=1}^d \left[\frac{\beta_i}{M_n}, \frac{\beta_i+1}{M_n}\right[, \boldsymbol{\beta} \in [\![0, M_n-1]\!]^d\right\}$.

Remark 3.6. The above rearrangement of hypercubes is similar to the one used for computing in place the Discrete Fast Fourier Transform: the bit reversal. In the special case where $M_n = 2^n$, the rearrangement simply exchanges layers i, *i.e.*, $[i/2^n, (i+1)/2^n[$, and i', *i.e.*, $[i'/2^n, (i'+1)/2^n[$, when i and i' are bit reversal permutations of each other. *I.E* when $i = \sum_{j=0}^{n-1} b_j 2^j$ and $i' = \sum_{j=0}^{N-1} b_j 2^{n-1-j}$.

Remark 3.7. For general M_n, the rearrangement of hypercubes is also a bit reversal but for a mixed basis. If $\lfloor M_n y' \rfloor = \sum_{j=1}^n b_j M_{j-1}$ with b_j in $[\![0, m_j-1]\!]$, then

$$H_n^*\left(\frac{1}{M_n}\sum_{j=1}^n b_j \frac{M_n}{M_j} + (y' - \frac{\lfloor M_n y' \rfloor}{M_n})\right) = y'.$$

We now state our main result as a self contained theorem.

Theorem 3.8 (Two-Scale Shuffle convergence)**.** *Let Ω be a bounded open domain of $\mathbb{R}^d$ with $d \geq 1$. Let $(u_\varepsilon)_{\varepsilon>0}$ be a bounded sequence of functions belonging to $\mathrm{L}^2(\Omega)$. Let $(p_n)_{n\in\mathbb{N}}$ be an increasing sequence of positive numbers that satisfy Assumption 3.1. Set for all $n \geq 0$ $M_n := p_n/p_0$ and for all $n \geq 1$ $m_n := p_n/p_{n-1}$. Let $(\varepsilon_k)_{k\in\mathbb{N}}$ be a decreasing sequence of positive real numbers* *converging to* 0 *such that the sequence* $(u_{\varepsilon_k})_{k\in\mathbb{N}}$ p_n*-two-scale converges to* u_{0,p_n} *for all non-negative integer* n.

Set

$$\begin{aligned}\widetilde{w}_n : \Omega\times[0,p_0]^d\times[0,1]^d &\to \mathbb{R}\\ (\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}') &\mapsto u_{0,p_n}\left(\boldsymbol{x}, p_0\lfloor M_n H_n(\boldsymbol{y}')\rfloor+\boldsymbol{y}\right).\end{aligned}$$

where H_n *is defined by Equations* (3.4).

Then, the sequence $\widetilde{w}_n$ *is a bounded martingale in* $\mathrm{L}^2(\Omega\times[0,p_0]^d\times[0,1]^d)$, *in the sense of Definition 2.10, for the filtration*

$$\mathcal{F}_n=\mathcal{B}(\Omega)\times\mathcal{B}([0,p_0]^d)\times\sigma\left\{\prod_{i=1}^d\left[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}\right[, \boldsymbol{\beta}\in[\![0,M_n-1]\!]^d\right\}. \quad (3.6)$$

And, the sequence $\widetilde{w}_n$ *converges both strongly in* $\mathrm{L}^2(\Omega\times[0,p_0]^d\times[0,1]^d)$ *and almost everywhere in* $\Omega\times[0,p_0]^d\times[0,1]^d$ *to* $\widetilde{w}_\infty$, *which we call the Two-Scale Shuffle limit. Moreover,*

$$\iiint_A \widetilde{w}_n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'\,\mathrm{d}\boldsymbol{y}\,\mathrm{d}\boldsymbol{x}=\iiint_A \widetilde{w}_\infty(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'\,\mathrm{d}\boldsymbol{y}\,\mathrm{d}\boldsymbol{x},$$

for all sets A *in* $\mathcal{F}_n$. *I.E., by Definition 2.7,* $\widetilde{w}_n=\mathbb{E}(\widetilde{w}_\infty|\mathcal{F}_n)$.

Proof. The $\widetilde{w}_n$ were constructed specifically so as to be a martingale for the filtration (3.6). To prove they are a martingale for the filtration $(\mathcal{F}_n)_{n\in\mathbb{N}}$, we only need to prove that for all non-negative integer n, for almost all $\boldsymbol{x}$ in Ω, almost all $\boldsymbol{y}$ in $[0,p_0]^d$ and for all $\boldsymbol{\beta}$ in $[\![0,M_n-1]\!]^d$, we have

$$\int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[}\widetilde{w}_{n+1}(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'=\int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[}\widetilde{w}_n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'.$$

I.E., we need to show that

$$\int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[} w_n(\boldsymbol{x},\boldsymbol{y},H_n(\boldsymbol{y}'))\,\mathrm{d}\boldsymbol{y}'=\int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[} w_{n+1}(\boldsymbol{x},\boldsymbol{y},H_{M_n,m_{n+1}}\circ H_n(\boldsymbol{y}'))\,\mathrm{d}\boldsymbol{y}'.$$

But H_n maps any hypercube $\prod_{i=1}^d[\beta_i/M_n,(\beta_i+1)/M_n[$ to another hypercube $\prod_{i=1}^d[\beta_i'/M_n,(\beta_i'+1)/M_n[$ and H_n is measure preserving. Therefore, we only need to prove that for almost all $\boldsymbol{x}$ in Ω, almost all $\boldsymbol{y}$ in $[0,p_0]^d$ and for all $\boldsymbol{\beta}$ in $[\![0,M_n-1]\!]^d$

$$\int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[} w_n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'=\int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[} w_{n+1}(\boldsymbol{x},\boldsymbol{y},H_{M_n,m_{n+1}}(\boldsymbol{y}'))\,\mathrm{d}\boldsymbol{y}'.$$

is satisfied. But this equality is equivalent to

$$\begin{aligned}
&\frac{1}{M_n^d} v_{p_n}(\boldsymbol{x},\boldsymbol{\beta},\boldsymbol{y}) = \\
&\qquad = \frac{1}{M_{n+1}^d} \sum_{\boldsymbol{\beta}'\in[\![0,m_{n+1}-1]\!]^d} v_{p_{n+1}}(\boldsymbol{x}, R_{M_n,m_{n+1}}(m_{n+1}\boldsymbol{\beta}+\boldsymbol{\beta}'),\boldsymbol{y}) = \\
&\qquad\qquad = \frac{1}{M_{n+1}^d} \sum_{\boldsymbol{\beta}'\in[\![0,m_{n+1}-1]\!]^d} v_{p_{n+1}}(\boldsymbol{x}, (\boldsymbol{\beta}+\boldsymbol{\beta}' M_n),\boldsymbol{y}),
\end{aligned}$$

which is true by Proposition 3.4. Therefore, the sequence $\widetilde{w}_n$ is a martingale for the filtration $(\mathcal{F}_n)_{n\in\mathbb{N}}$.

By Proposition 2.3, this martingale is bounded in L^2. It converges both strongly in $\mathrm{L}^2(\Omega\times[0,p_0]^d\times[0,1]^d)$ and almost everywhere to a function $\widetilde{w}_\infty$, see [7, Corollary 7.22]. ☐

Corollary 3.9. *It is possible to recover u_{0,p_n} from the Two-Scale Shuffle limit $\widetilde{w}_\infty$. First, for all $\boldsymbol{\beta}$ in $[\![0,M_n-1]\!]^d$, all $\boldsymbol{y}'$ in $\prod_{i=1}^d[\beta_i/M_n,(\beta_i+1)/M_n[$, and almost all $(\boldsymbol{x},\boldsymbol{y})$ in $\Omega\times[0,p_0]^d$, we have*

$$\widetilde{w}_n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}') = M_n^d \int_{\prod_{i=1}^d[\frac{\beta_i}{M_n},\frac{\beta_i+1}{M_n}[} \widetilde{w}_\infty(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')\,\mathrm{d}\boldsymbol{y}'$$

because $\widetilde{w}_n=\mathbb{E}(\widetilde{w}_\infty|\mathcal{F}_n)$. Since the shuffle function H_n is one to one from $[0,1[^d$ to $[0,1[^d$, see Remark 3.7, we have $w_n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{y}')=\widetilde{w}_n(\boldsymbol{x},\boldsymbol{y},H_n^{-1}(\boldsymbol{y}'))$. Finally, $u_{0,p_n}(\boldsymbol{x},\boldsymbol{y})$ is equal to the constant value taken by $\boldsymbol{y}'\mapsto w_n(\boldsymbol{x},\boldsymbol{y}-p_0\lfloor\boldsymbol{y}/p_0\rfloor,\boldsymbol{y}')$ when $\boldsymbol{y}'$ belongs to the hypercube $[\lfloor\boldsymbol{y}/p_0\rfloor/M_n,(\lfloor\boldsymbol{y}/p_0\rfloor+1)/M_n[$.

4 Application: heat equation in multilayers

In this section, we consider the multilayer heat equation with three spatial dimensions which we homogenize along the vertical space variable, *i.e.*, along the direction perpendicular to the layers.

In [13], the author established the equations satisfied by the two-scale limits of the heat equation in multilayers with transmission conditions between adjacent layers. When the magnitude of the interlayer conductivity between adjacent layers is weak, see [13, §6.1], the two-scale limit depends on the number of layers present in the homogenization period, *i.e.*, on the scale factors p_n. For given values of the slow variables $(\boldsymbol{x},t)$, the two scale limit is piecewise constant in its scalar fast variable y and takes as many values as there are layers in a single homogenization cell. Our goal is to establish the

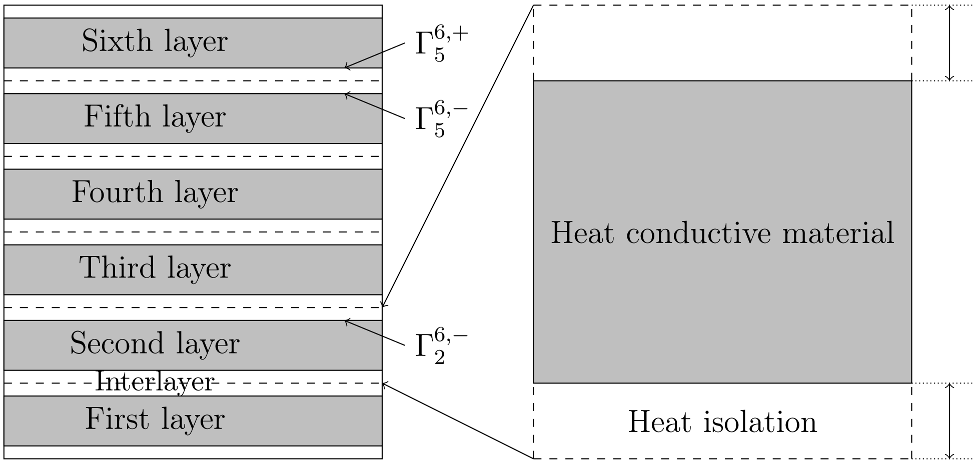

Figure 3: The multilayer geometry, six layers: $N = 6$.

equation satisfied by the limit of two-scale limits, *i.e.*, the Two-Scale Shuffle limit, as defined in Theorem 3.8.

To do so, we first recall previously known results in §4.1, then derive new results using Two-Scale Shuffle Convergence in §4.2.

4.1 The two-scale limit of the multilayer heat equation

We start by recalling some results we obtained in [13]. To avoid unnecessary complications, we consider here a simpler problem than the one considered in [13, System (4.1)]. Let Ω be $B\times]0,1[$ where B is a convex bounded open subset of $\mathbb{R}^2$ with smooth boundary. Let δ, $0 < \delta < 1/2$. Let I be the interval $]\delta, 1-\delta[$. For all N, let I_N be $\bigcup_{j=0}^{N-1}](j+\delta)/N, (j+1-\delta)/N[$. Let Ω^N be the domain $B\times I_N$. Let $\Gamma_j^{N,+} = B\times\{(j+\delta)/N\}$ and $\Gamma_j^{N,-} = B\times\{(j-\delta)/N\}$. Let $\Gamma^{N,+} = \bigcup_{j=1}^{N-1}\Gamma_j^{N,+}$ and $\Gamma^{N,-} = \bigcup_{j=1}^{N-1}\Gamma_j^{N,-}$. Let $\Gamma_e = \partial B\times]0,1[\cup\Gamma_0^{N,+}\cup\Gamma_N^{N,-}$. Let γ be the application on $\partial\Omega^N$ that maps u in $\mathrm{H}^1(\Omega^N)$ to its trace on $\partial\Omega^N$. Let γ' be the trace operator swapped between $\Gamma_j^{N,+}$ and $\Gamma_j^{N,-}$: *i.e.*, $\gamma' u(\hat{\boldsymbol{x}}, (j\pm\delta)/N) = \gamma u(\hat{\boldsymbol{x}}, (j\mp\delta)/N)$ for all $\hat{\boldsymbol{x}}$ in B and all j in $\llbracket 1, N-1\rrbracket$. See Figure 3 where we schematized the three dimensional domain Ω^N by projecting it onto the two-dimensional plane.

Let A, K and J be positive reals: A represents the heat conductivity inside Ω^N, and J is the magnitude of the surfacic interlayer conductivity. For all positive integer N, we consider the multilayer heat equation

$$\frac{\partial u_N}{\partial t} - A\,\triangle\, u_N = 0 \text{ in } \Omega^N\times\mathbb{R}^+ \tag{4.1a}$$

with the boundary conditions

$$A\frac{\partial u_N}{\partial \boldsymbol{\nu}} = \begin{cases} 0 & \text{on } \Gamma_e \times \mathbb{R}^+ \\ -\frac{K}{N}\gamma u_N + \frac{J}{N}(\gamma' u_N - \gamma u_N) & \text{on } (\Gamma^{N,+} \cup \Gamma^{N,-}) \times \mathbb{R}^+, \end{cases} \tag{4.1b}$$

and the initial condition

$$u_N(\cdot, 0) = u_N^0. \tag{4.1c}$$

We also define the energy

$$E^N(v) = \frac{A}{2}\int_{\Omega^N} \|\nabla v(\boldsymbol{x})\|^2 \,\mathrm{d}\boldsymbol{x} + \frac{K}{2N}\int_{\Gamma^{N,+}\cup\Gamma^{N,-}} |\gamma v|^2 \,\mathrm{d}\sigma(\boldsymbol{x}) \\ + \frac{J}{2N}\sum_{j=1}^{N-1}\int_B \left| v(\hat{\boldsymbol{x}}, \frac{j+\delta}{N}) - v(\hat{\boldsymbol{x}}, \frac{j-\delta}{N})\right|^2 \mathrm{d}\hat{\boldsymbol{x}},$$

for all v in $H^1(\Omega^N)$. We suppose

$$\sup_N E^N(u_N^0) < +\infty,$$

and denote by $u_{0,M}^0$ the M-two-scale limit of the initial conditions u_N^0. We have the energy equality

$$E^N(u_N(\cdot, T)) + \int_0^T \int_{\Omega^N} \left|\frac{\partial u_N}{\partial t}\right|^2 \mathrm{d}\boldsymbol{x}\,\mathrm{d}t = E^N(u_N(\cdot, T)),$$

for all $T \geq 0$. Because of the energy bound, for all $\boldsymbol{x}$ in Ω and all j in $\mathbb{Z}/M\mathbb{Z}$, the function $y \mapsto u_{0,M}^0(\boldsymbol{x}, y)$ is constant in the interval $]j+\delta, j+1-\delta[$. Moreover, that function is M-periodic in y. We denote by $u_{0,M_n,j}^0(\boldsymbol{x})$ the value taken by the function $y \mapsto u_{0,M}^0(\boldsymbol{x}, y)$ in the interval $]j+\delta, j+1-\delta[$.

Using two-scale convergence [1, 10] and its variant on periodic surfaces [8, 9, 2], the properties of the two-scale limit of $(u^N)_{N\in\mathbb{N}}$, solutions to the multilayer heat system (4.1) with $J \neq 0$, were established in [13, Theorem 6.1].

Let $(M_n)_{n\geq 0}$ be a sequence of positive integers such that $M_0 = 1$ and such that M_{n+1} is always an entire multiple of M_n. For all $(\boldsymbol{x}, t)$ in $\Omega \times \mathbb{R}^+$, the M_n-two-scale limit $y \mapsto u_{0,M_n}(\boldsymbol{x}, t, y)$ takes M_n values: it is constant in each interval $]j+\delta, j+1-\delta[$. For j in $\mathbb{Z}/M_n\mathbb{Z}$, we note $u_{0,M_n,j}(\boldsymbol{x}, t)$ the value of $u_{0,M_n}(\boldsymbol{x}, t, \cdot)$ in this interval. We have $u_{0,M_n,j+M_n}(\boldsymbol{x}, t) = u_{0,M_n,j}(\boldsymbol{x}, t)$. These functions satisfy, for all j in $\mathbb{Z}/M_n\mathbb{Z}$, the weak formulation of

$$\frac{\partial u_{0,M_n,j}}{\partial t} - A \triangle_{\mathrm{T}} u_{0,M_n,j} + \frac{2K}{1-2\delta} u_{0,M_n,j} + \\ + \frac{J}{1-2\delta}(2u_{0,M_n,j} - u_{0,M_n,j+1} - u_{0,M_n,j-1}) = 0, \tag{4.2a}$$

in $\Omega\times\mathbb{R}^+$, and where $\triangle_{\mathrm{T}}=\frac{\partial^2}{\partial x_1^2}+\frac{\partial^2}{\partial x_2^2}$, $\nabla_{\mathrm{T}}=[\frac{\partial}{\partial x_1},\frac{\partial}{\partial x_2}]^{\mathrm{T}}$. And with boundary conditions

$$\frac{\partial u_{0,M_n,j}}{\partial \boldsymbol{\nu}}=0 \text{ on } (\partial B\times]0,1[)\times\mathbb{R}^+, \tag{4.2b}$$

and initial condition

$$u_{0,M_n,j}(\cdot,0)=u^0_{0,M_n,j} \text{ in } B\times]0,1[. \tag{4.2c}$$

We have recalled previously known results on the properties of the two-scale limits of the multilayer heat equation. In the next section, we establish the properties satisfied by the Two-Scale Shuffle limit of the multilayer heat equation.

4.2 The two-scale shuffle limit of the multilayer heat equation

We now use Theorem 3.8 to have the two-scale limits themselves converge. We choose $M_n=2^n$ to avoid complications at first. We establish the following:

Theorem 4.1. *Let $\widetilde{w_\infty}$ be the Two-Scale Shuffle limit defined from $(u_{0,2^n})_{n\in\mathbb{N}}$ as in Theorem 3.8. For all $(\boldsymbol{x},t)$ in $\Omega\times\mathbb{R}^+$, and y' in $[0,1]$. The function $\widetilde{w}_\infty(\boldsymbol{x},t,\cdot,y')$ is constant in the interval $]\delta,1-\delta[$. If we denote by $\widetilde{w}_\infty(\boldsymbol{x},t,y')$ the value of $\widetilde{w}_\infty(\boldsymbol{x},t,\cdot,y')$ inside the interval $]\delta,1-\delta[$, the Two-Scale Shuffle limit $\widetilde{w}_\infty$ is a weak solution to:*

$$\begin{aligned}\frac{\partial\widetilde{w}_\infty}{\partial t}(\boldsymbol{x},t,y')-A\,\triangle_{\mathrm{T}}\,\widetilde{w}_\infty(\boldsymbol{x},t,y')+\frac{2K}{1-2\delta}\widetilde{w}_\infty(\boldsymbol{x},t,y')\\ +\frac{J}{1-2\delta}(2\widetilde{w}_\infty(\boldsymbol{x},t,y')-\widetilde{w}_\infty(\boldsymbol{x},t,\tau^+(y'))-\widetilde{w}_\infty(\boldsymbol{x},t,\tau^-(y')))=&0,\end{aligned} \tag{4.3a}$$

in $\Omega\times\mathbb{R}^+\times]0,1[$, and where, for all non-negative integers j:

$$\tau^+(y')=y'+3\cdot2^{-(j+1)}-1 \text{ when } 1-2^{-j}\le y'<1-2^{-(j+1)},$$
$$\tau^-(y')=y'-3\cdot2^{-(j+1)}+1 \text{ when } 2^{-(j+1)}\le y'<2^{-j}.$$

with boundary conditions

$$\frac{\partial\widetilde{w}_\infty}{\partial\boldsymbol{\nu}}=0 \text{ on } (\partial B\times]0,1[)\times\mathbb{R}^+\times]0,1[, \tag{4.3b}$$

and initial condition

$$\widetilde{w}_\infty(\cdot,0,\cdot)=\widetilde{w}^0_\infty.$$

where $\widetilde{w}^0_\infty$ is the Two-Scale Shuffle Limit of the initial conditions and where, as an abuse of notations, we denote by $\widetilde{w}^0_\infty(\boldsymbol{x},t,y')$ the constant value taken by $y\mapsto\widetilde{w}^0_\infty(\boldsymbol{x},t,y,y')$ in the interval $]\delta,1-\delta[$.

Proof. Let n in $\mathbb{N}$ and β belongs to $[\![0, 2^n - 1]\!]$. Let the w_n be defined as in §3.3, and the $\widetilde{w}_n$ be defined from the 2^n-two scale limits $u_{0,2^n}$ as in Theorem 3.8. Both the $\widetilde{w}_n$ and the w_n are functions defined over $(B\times]0,1[) \times \mathbb{R}^+\times]0,1[\times]0,1[$. For all $(\boldsymbol{x}, t)$ in $(B\times]0,1[) \times \mathbb{R}^+$, and y' in $]0,1[$, the application $y \mapsto \widetilde{w}_n(\boldsymbol{x}, t, y, y')$ is constant on $]\delta, 1-\delta[$. As an abuse of notations, let's also denote by $\widetilde{w}_n(\boldsymbol{x}, t, y')$ the value of $\widetilde{w}_n(\boldsymbol{x}, t, y', y)$ when y belongs to $]\delta, 1-\delta[$. We use the same abuse of notations for the w_n. Consider a test function φ belonging to $\mathcal{C}^\infty(\overline{\Omega}\times\mathbb{R}^+)$. Set $\psi(\boldsymbol{x}, t, y) = \varphi(x,t)\mathbb{1}\{y \in [\frac{\beta}{2^n}, \frac{\beta+1}{2^n}[\}$. Let $Q_T = \Omega \times \mathbb{R}^+$. Then, since the $u_{0,2^n,j}$ satisfy the weak formulation of (4.2), we have:

$$
\begin{aligned}
&\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \frac{\partial w_n}{\partial t}(\boldsymbol{x}, t, y')\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&+A\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \nabla_{\mathrm{T}} w_n(\boldsymbol{x}, t, y')\cdot\nabla_{\mathrm{T}}\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&+\frac{2K}{1-2\delta}\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} w_n(\boldsymbol{x}, t, y')\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&+\frac{J}{1-2\delta}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} 2w_n(\boldsymbol{x}, t, y')\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&-\frac{J}{1-2\delta}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} (w_n(\boldsymbol{x}, t, y'+2^{-n}) + w_n(\boldsymbol{x}, t, y'-2^{-n}))\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t = 0,
\end{aligned}
$$

where, to simplify notations, we consider the function w_n to be 1-periodic in y'. Therefore, for all β in $[\![0, 2^n - 1]\!]$,

$$
\begin{aligned}
&\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \frac{\partial \widetilde{w}_n}{\partial t}(\boldsymbol{x}, t, y')\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&+A\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \nabla_{\mathrm{T}} \widetilde{w}_n(\boldsymbol{x}, t, y')\cdot\nabla_{\mathrm{T}}\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&+\frac{2K}{1-2\delta}\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \widetilde{w}_n(\boldsymbol{x}, t, y')\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&+\frac{J}{1-2\delta}\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} 2\widetilde{w}_n(\boldsymbol{x}, t, y')\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&-\frac{J}{1-2\delta}\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \widetilde{w}_n(\boldsymbol{x}, t, H_n^{*-1}(H_n^*(y')+2^{-n}))\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\
&-\frac{J}{1-2\delta}\iint_{Q_T}\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \widetilde{w}_n(\boldsymbol{x}, t, H_n^{*-1}(H_n^*(y')-2^{-n}))\cdot\varphi(\boldsymbol{x}, t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t. = 0
\end{aligned}
\tag{4.4}
$$

Here H_n^* is simply the bit reversal of the first n coefficients in the binary expansion. Thus:

$$H_n^{*-1}(H_n^*(y'+2^{-n})) = \begin{cases} y' + 3\cdot 2^{-(j+1)} - 1 & \text{if } 1-2^{-j} \le y' < 1-2^{-(j+1)}, \\ & \text{for } 0 \le j \le n-1, \\ y' - 1 + 2^{-n} & \text{if } 1-2^{-n} \le y' < 1. \end{cases} \tag{4.5}$$

And

$$H_n^{*-1}(H_n^*(y') - 2^{-n}) = \begin{cases} y' - 3\cdot 2^{-(j+1)} + 1 & \text{if } 2^{-(j+1)} \le y' < 2^{-j}, \\ & \text{for } 0 \le j \le n-1, \\ y' + 1 - 2^{-n} & \text{if } 0 \le y' < 2^{-n}. \end{cases} \tag{4.6}$$

Since $\varphi(\boldsymbol{x},t)\mathbb{1}\{y' \in [\frac{\beta}{2^n}, \frac{\beta+1}{2^n}[\}$ is $\mathcal{F}_n$-measurable and $\widetilde{w}_n = \mathbb{E}(\widetilde{w}_\infty|\mathcal{F}_n)$, Equality (4.4) remains valid after replacing $\widetilde{w}_n$ by $\widetilde{w}_\infty$. Therefore,

$$\begin{aligned} &\iiint_{Q_T} \int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \frac{\partial \widetilde{w}_\infty}{\partial t}(\boldsymbol{x},t,y') \cdot \varphi(\boldsymbol{x},t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\ &+A \iiint_{Q_T} \int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \nabla_{\mathrm{T}}\widetilde{w}_\infty(\boldsymbol{x},t,y') \cdot \nabla_{\mathrm{T}}\varphi(\boldsymbol{x},t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\ &+\frac{2K}{1-2\delta} \iiint_{Q_T} \int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} \widetilde{w}_\infty(\boldsymbol{x},t,y') \cdot \varphi(\boldsymbol{x},t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\ &+\frac{J}{1-2\delta} \int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} 2\widetilde{w}_\infty(\boldsymbol{x},t,y') \cdot \varphi(\boldsymbol{x},t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t \\ -\frac{J}{1-2\delta} &\int_{[\frac{\beta}{2^n},\frac{\beta+1}{2^n}[} (\widetilde{w}_\infty(\boldsymbol{x},t,\tau^+(y')) - \widetilde{w}_\infty(\boldsymbol{x},t,\tau^-(y'))) \cdot \varphi(\boldsymbol{x},t)\,\mathrm{d}y'\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}t = 0 \end{aligned}$$

for all n in $\mathbb{N}$ and β in $[\![1, 2^n-2]\!]$. Choose y' in $]0,1[$, for any positive integer n, set $\beta = \lfloor 2^n y' \rfloor$ and take the limit in the above equality divided by 2^{-n} as n tends to $+\infty$. $\square$

If instead of setting $M_n = 2^n$, we consider a general sequence $(M_n)_{n\in\mathbb{N}}$, the same reasonning holds. When M_n is 2^n, the shuffling of layers is the bit reversal of the first n coefficients of the binary representation of y, thus involutive. This is not the case for general M_n and we must use Remark 3.7. Therefore, utmost care must be taken to compute the analogues of (4.5) and (4.6). We provide the limit in the general case without proof. In that case, we have

$$H_n^{*-1}(H_n^*(y')+\frac{1}{M_n}) = \begin{cases} y' - \sum_{l=1}^{j}\frac{1}{M_l} + \frac{1}{M_{j+1}} & \text{if } 1-\frac{1}{M_j} \le y' < 1-\frac{1}{M_{j+1}}, \\ & \text{for } 0 \le j \le n-1, \\ y' - 1 + \frac{1}{M_n} & \text{if } 1-\frac{1}{M_n} \le y' < 1. \end{cases}$$

$$H_n^{*-1}(H_n^*(y')-\frac{1}{M_n}) = \begin{cases} y' + \sum_{l=1}^{j}\frac{1}{M_l} - \frac{1}{M_{j+1}} & \text{if } \frac{1}{M_j} \le y' < \frac{1}{M_{j+1}}, \\ & \text{for } 0 \le j \le n-1, \\ y' + 1 - \frac{1}{M_n} & \text{if } 0 \le y' < \frac{1}{M_n}. \end{cases}$$

and the limit equation (4.3a) remains valid if we set instead

$$\tau^+(y') = y' - \sum_{l=1}^{j}\frac{1}{M_l} + \frac{1}{M_{j+1}} \text{ when } 1-\frac{1}{M_j} \le y' < 1-\frac{1}{M_{j+1}}, \tag{4.7a}$$

$$\tau^-(y') = y' + \sum_{l=1}^{j}\frac{1}{M_l} - \frac{1}{M_{j+1}} \text{ when } \frac{1}{M_{j+1}} \le y' < \frac{1}{M_j}, \tag{4.7b}$$

for all non-negative integer j.

5 Conclusion

We have proven in this paper, see Theorem 3.8, that the two-scale limits of a given sequence of functions, computed for periods that are entire multiple of the previous ones, form a bounded martingale and thus converge both strongly in L^2 and almost everywhere. From the limit, called the Two-Scale Shuffle limit, one can recover any element in the sequence of two-scale limits: this limit contains all the information contained in the whole sequence of two-scale limits, see Corollary 3.9. For a good choice of increasing periods, this limits captures everything that happens at any length scale that is an entire multiple of ε.

Unfortunately, this limit does not capture all phenomena with a period linear in ε: it cannot capture phenomena with an irrational scale factor. The construction of the martingale depends on the assumption that p_{n+1} is always an entire multiple of p_n. If there are two interesting scales whose ratio is irrational then no choice of periodic scale carry the information for both scales.

We applied the notion of the Two-Scale Shuffle limit to the heat equation on multilayers with transmission conditions between adjacent layers. We then considered the solutions to these equations and established the equation satisfied by their Two-Scale Shuffle limit.

To establish the convergence of the two-scale limit, we used the shuffle of hypercubes described in §3.3. Unfortunately, because of this shuffle, it is not easy to reach an intuitive understanding of the Two-Scale Shuffle limit. Results on the existence of the limit in the setting of §3.2 would not have that drawback. Solving Problem 3.5 would be a first step to obtain a limit in this setting.
